

WARNING to ALL Pet Owners:

Due to a decision made by the EPA in 2008, manufacturers of rat and mice poisons are using Bromethalin as the new toxin of choice. Contrary to historic use of anticoagulants in rodenticides, which can be tested for and treated, Bromethalin has NO TEST to detect its presence and NO ANTIDOTE.

Bromethalin is a neurotoxin which causes bleeding in the brain and can lead to altered mental states of hyper-excitation, depression, staggering, seizures, and coma. Severity of symptoms is dose dependent, but symptoms occur faster, are much harder to diagnose, and much more difficult to treat.

There are still anticoagulant rodenticides available, primarily manufactured by D-Con. As with all poisons, read the label carefully, and avoid even accidental exposure and death by selecting products wisely and taking great care to avoid ingestion by any unattended animal or child.
